

Earth 460 Classnotes (Set 5)

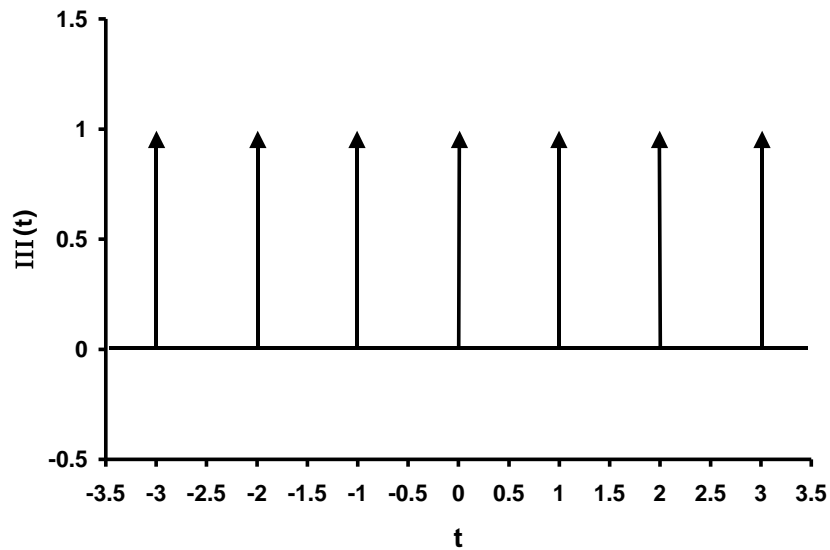

II.) Time Series Analysis – Discrete Signals

A.) Sampling

1.) Sampling or Replicating Function (Dirac Delta Comb) $\text{III}(t)$

a.) The sampling function is an infinite series of Dirac delta functions

uniformly spaced at a unit interval: $\text{III}(t) = \sum_{n=-\infty}^{+\infty} \delta(t-n)$

b.) Properties of $\text{III}(t)$

1.) $\text{III}(at) = \frac{1}{|a|} \sum_{n=-\infty}^{+\infty} \delta(t - n/a)$

2.) $\text{III}(t+n) = \text{III}(t)$ where n is an integer (i.e., $\text{III}(t)$ is periodic with unit period)

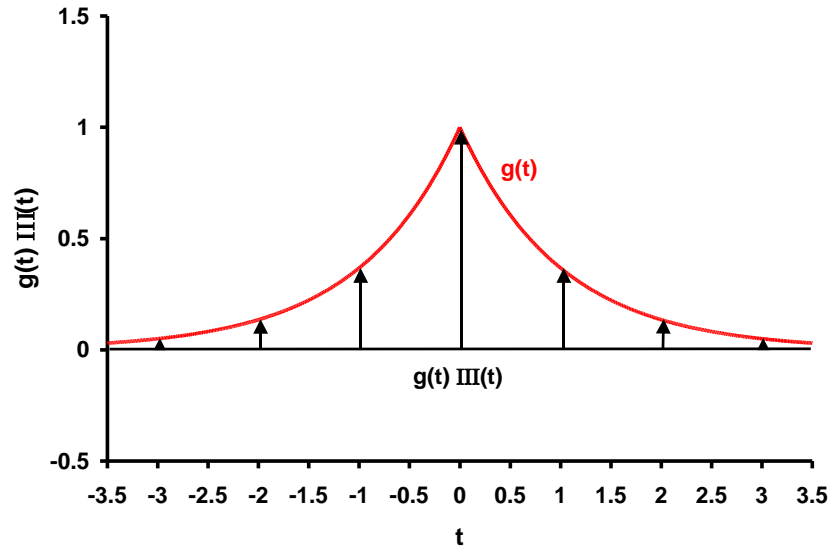

c.) The periodic sampling property follows from a generalization of the

delta function: $g(t) \text{III}(t) = \sum_{n=-\infty}^{+\infty} g(n) \delta(t-n)$.

1.) $g(t)$ is sampled at a unit interval.

2.) Information about $g(t)$ in the interval between integers is removed, but $g(t)$ values at integer values are retained.

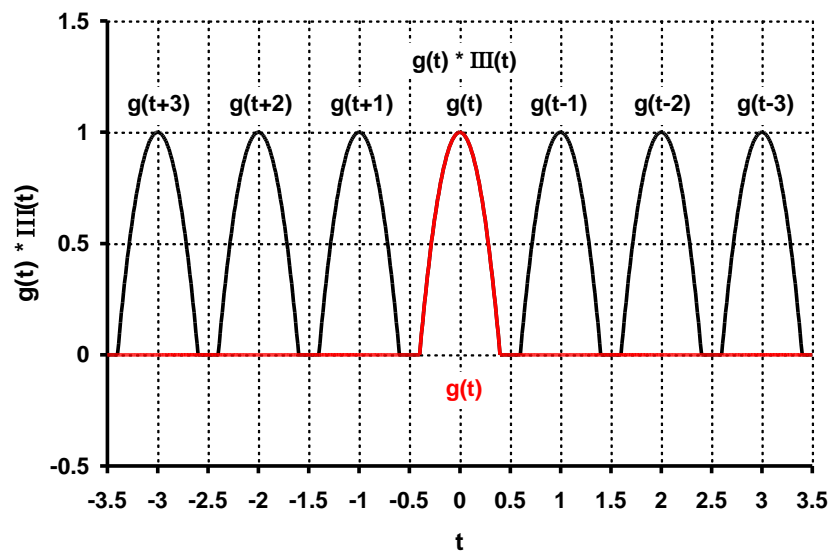

Earth 460 Classnotes (Set 5)

d.) Periodic replication property results from the convolution of $g(t)$ with

$$III(t): g(t) * III(t) = \sum_{n=-\infty}^{+\infty} g(t) * \delta(t-n) = \sum_{n=-\infty}^{+\infty} g(t-n).$$

A replication of $g(t)$ is generated at unit intervals along the t axis (i.e., a periodic function).

Earth 460 Classnotes (Set 5)

e.) Fourier transform of $\text{III}(t)$

Using a sequence of test functions, it can be shown that $\text{III}(t) \Leftrightarrow \text{III}(f)$.

2.) The Effects of Sampling a Continuous Signal

a.) $g(t)$ is sampled at a uniform interval Δt . The discrete time signal $d(t)$

is given by $d(t) = \sum_{n=-\infty}^{+\infty} g(n\Delta t) \delta(t - n\Delta t)$. Using

$$\text{III}(t/\Delta t) = \Delta t \sum_{n=-\infty}^{+\infty} \delta(t - n\Delta t), \text{ then } d(t) = (\Delta t)^{-1} g(t) \text{III}(t/\Delta t).$$

b.) The Fourier transform of the uniformly sampled time signal

1.) Using the scaling theorem: $\text{III}(t/\Delta t) \Leftrightarrow \Delta t \text{III}(\Delta t f)$

2.) With $g(t) \Leftrightarrow G(f)$ and the convolution relationship, we have

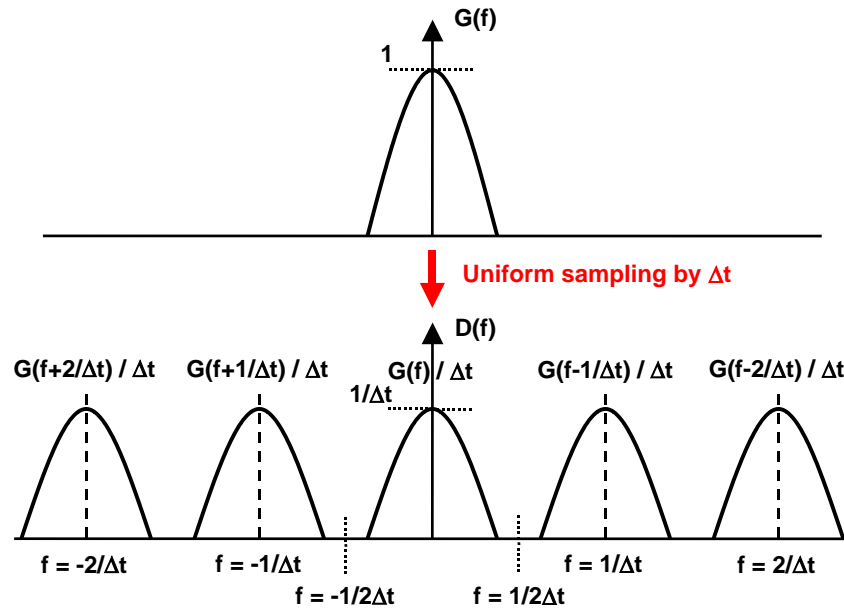

$$d(t) = (\Delta t)^{-1} g(t) \text{III}(t/\Delta t) \Leftrightarrow D(f) = G(f) * \text{III}(\Delta t f)$$

3.) Using $\text{III}(\Delta t f) = (\Delta t)^{-1} \sum_{n=-\infty}^{+\infty} \delta(f - n/\Delta t)$, then

$$\begin{aligned} D(f) &= (\Delta t)^{-1} G(f) * \left[\sum_{n=-\infty}^{+\infty} \delta(f - n/\Delta t) \right] = (\Delta t)^{-1} \sum_{n=-\infty}^{+\infty} G(f) * \delta(f - n/\Delta t) \\ &= (\Delta t)^{-1} \sum_{n=-\infty}^{+\infty} G(f - n/\Delta t) \end{aligned}$$

4.) Sampling a time signal at a uniform interval Δt causes the original Fourier transform of the continuous signal to replicate itself in the frequency domain at an interval of $1/\Delta t$ (i.e., a periodic function with a fundamental period $1/\Delta t$) and be scaled by a factor of $1/\Delta t$

Earth 460 Classnotes (Set 5)

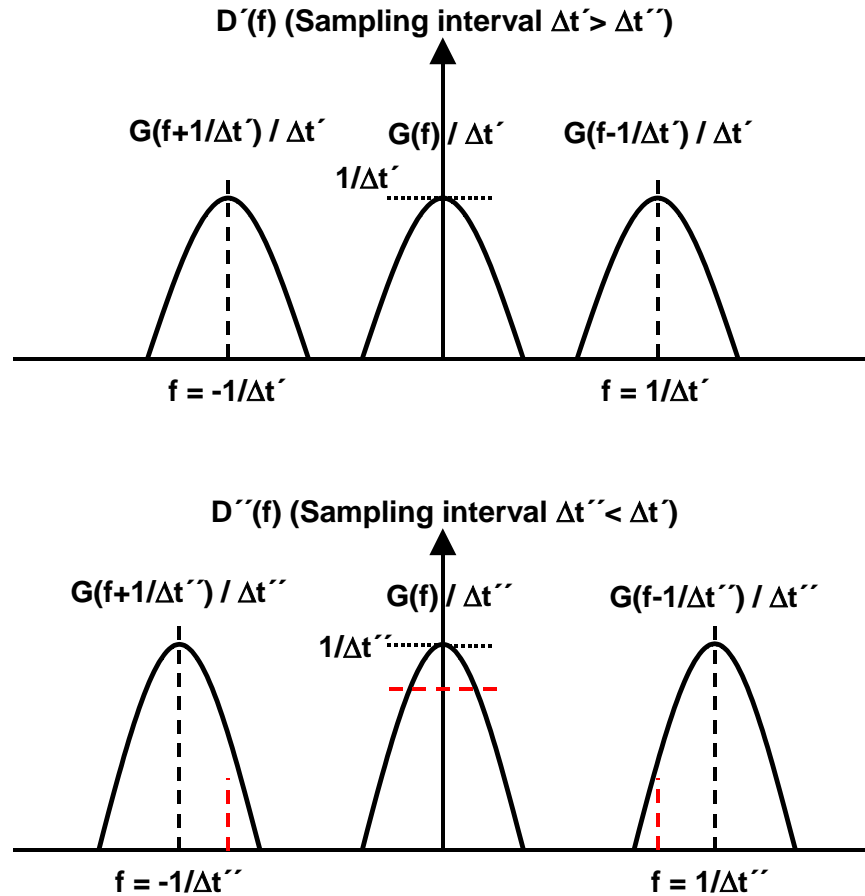

(Note: If $|G(f)| > 0$ for $|f| > 1/2\Delta t$, then overlapping of replications occurs.)

3.) The Effects of Changing the Sampling Interval Δt

- a.) As Δt is decreased, $g(t)$ is sampled on a finer interval. Hence, more information about $g(t)$ is retained.
- b.) Effect on the Fourier transform of the sampled signal
 - 1.) The sampling interval is decreased from $\Delta t'$ to $\Delta t''$ (i.e., $\Delta t' > \Delta t''$).
 - 2.) The replication interval of the Fourier transform ($1/\Delta t$) increases – the replications of $G(f)$ move farther apart.
 - 3.) The amplitude scaling factor $1/\Delta t$ increases.

Earth 460 Classnotes (Set 5)

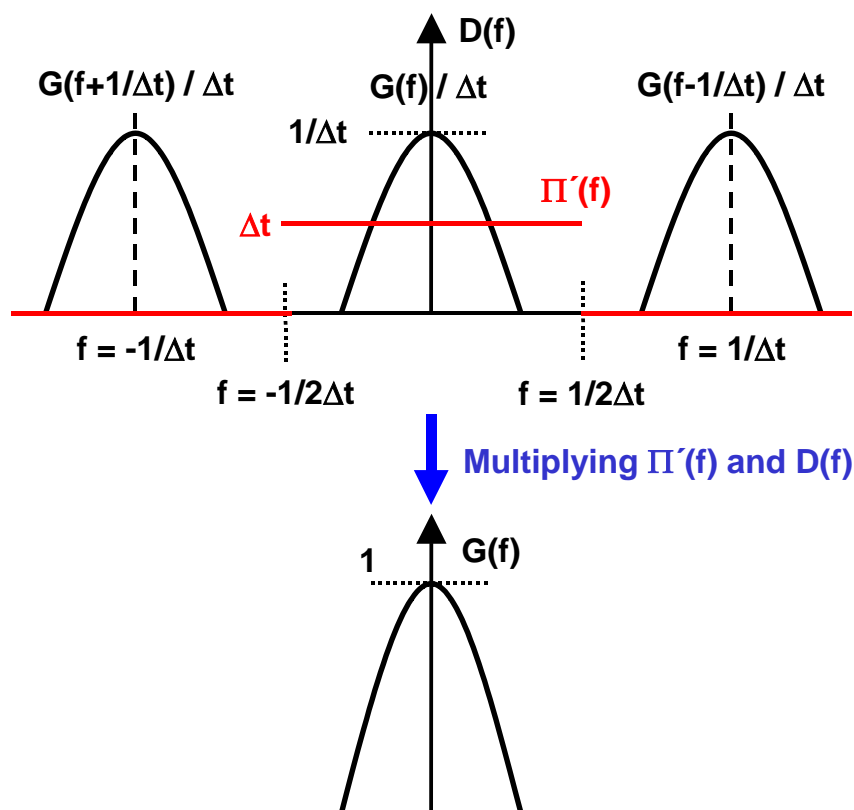

- 4.) The converse occurs if the sampling interval is increased.
- c.) If $G(f)$ is band-limited (i.e., $G(f) = 0$ for $f > f_{up}$ where f_{up} is the highest nonzero frequency component of $G(f)$), then it is possible to select a sampling interval Δt such that the replications do not overlap. This condition occurs when $f_{up} < 1/2\Delta t$.
- 4.) Sampling Theorem
- a.) By sampling $g(t)$ at a uniform interval Δt , information about the signal between the sampling points is lost. However, it is possible to completely recovery $g(t)$ after sampling under certain conditions.

Earth 460 Classnotes (Set 5)

- b.) Consider $D(f)$, the Fourier transform of $g(t)$ after being discretely sampled at an interval Δt . Suppose that the replications of $G(f)$ do not overlap (i.e., $G(f)$ is bandlimited such that $G(f) = 0$ for $f > 1/2\Delta t$).
- c.) Multiplying $D(f)$ by an appropriate boxcar function will reproduce $G(f)$.

That boxcar function is $\Pi'(f) = \Delta t \Pi(\Delta t f) = \begin{cases} \Delta t, & |f| \leq 1/2\Delta t \\ 0, & |f| > 1/2\Delta t \end{cases}$.

Hence, $\Pi'(f) D(f) = [\Delta t \Pi(\Delta t f)] \left[(\Delta t)^{-1} \sum_{n=-\infty}^{+\infty} G(f - n/\Delta t) \right] = G(f)$

Earth 460 Classnotes (Set 5)

d.) This frequency domain process is equivalent to convolving $d(t)$ with a sinc function in the time domain. Since $\text{sinc}(t/\Delta t) \Leftrightarrow \Delta t \Pi(\Delta t f)$, then $g(t) = d(t) * \text{sinc}(t/\Delta t) \Leftrightarrow D(f) \Delta t \Pi(\Delta t f) = G(f)$.

e.) In summary, the sampling theorem states: No information is lost by a uniform sampling Δt if the highest non-zero frequency component in the signal is less than $1/2\Delta t$.

- 1.) For a given sampling interval Δt , the quantity $1/2\Delta t$ is called the Nyquist frequency (i.e., $f_N = 1/2\Delta t$)
- 2.) This criterion is equivalent to requiring more than two samples per cycle for the highest non-zero frequency component.
- 3.) Since such a sampling interval gives complete information about $g(t)$, nothing further is gained by a finer sampling.

5.) Spatial Sampling

- a.) The concepts developed above for the discrete sampling of continuous time signals can be directly applied to the effect of discrete spatial sampling.
- b.) For a collection of uniformly spaced seismic/GPR traces (e.g., CMP gather, reflection profile), the spatial Nyquist wave number is $k_N = 1/2\Delta x$ where Δx is the incremental offset/distance between adjacent traces.

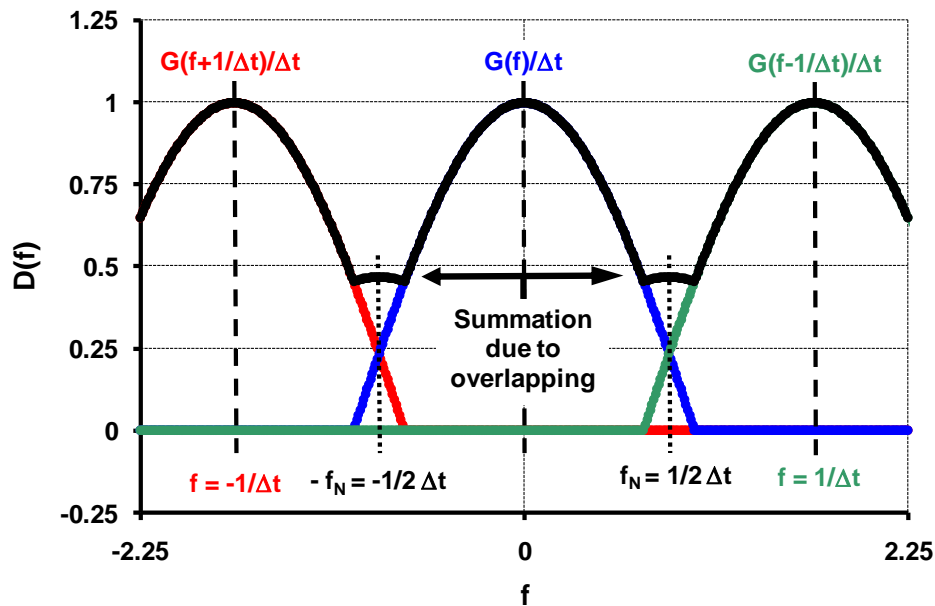

B.) Aliasing

1.) Nature of Aliasing

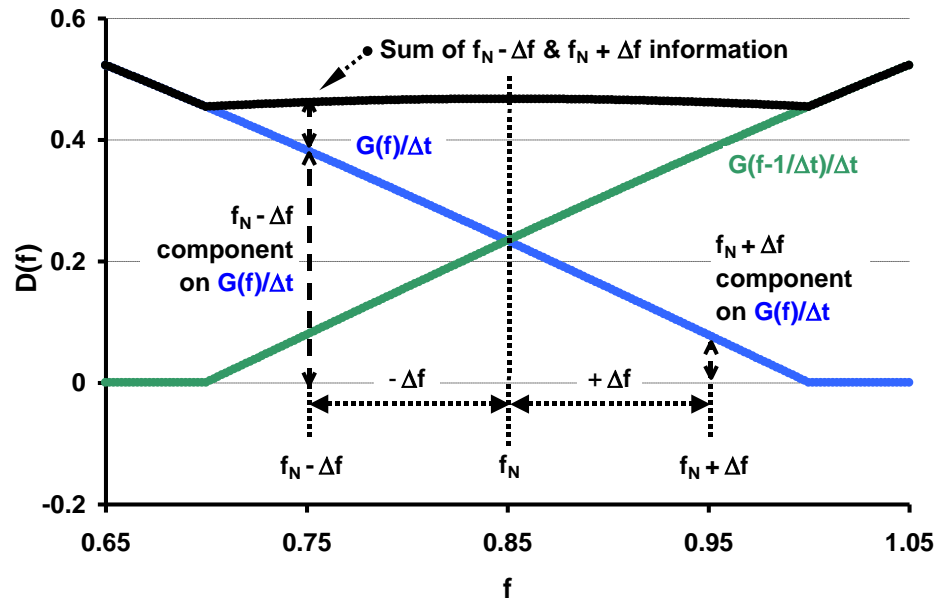

- a.) Suppose a signal $g(t)$ is sampled such that it contains non-zero frequency components greater than f_N .

Earth 460 Classnotes (Set 5)

- b.) Replications of $G(f)$ due to the sampling process overlap. This results in a summation in the overlap region that distorts the information contained in these frequency components
- c.) Higher frequency from the adjacent replication contaminates lower frequency components such that the information in the $f_N + \Delta f$ component is indistinguishable from the $f_N - \Delta f$ component (the higher frequency component is “aliased”). For $D(f)$, the summation of these two components is found at $f_N - \Delta f$.
- d.) This effect is equivalent to a “folding back” of the higher frequency information about f_N and combined with the lower frequencies.

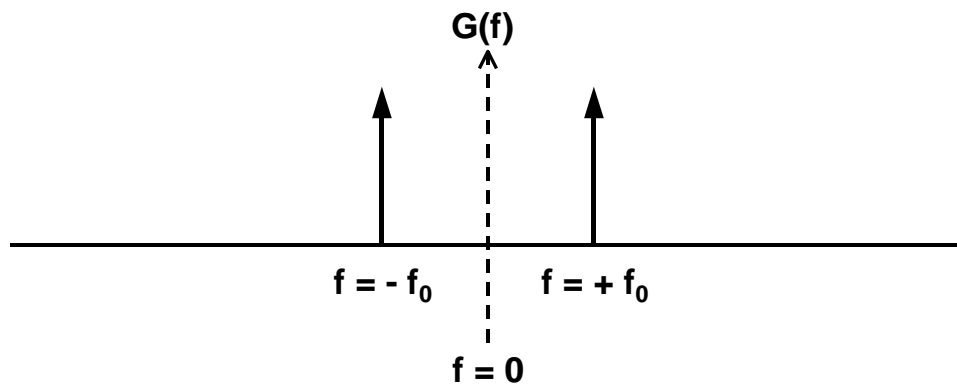

Earth 460 Classnotes (Set 5)

2.) Effects of Aliasing on a Specific Frequency Component

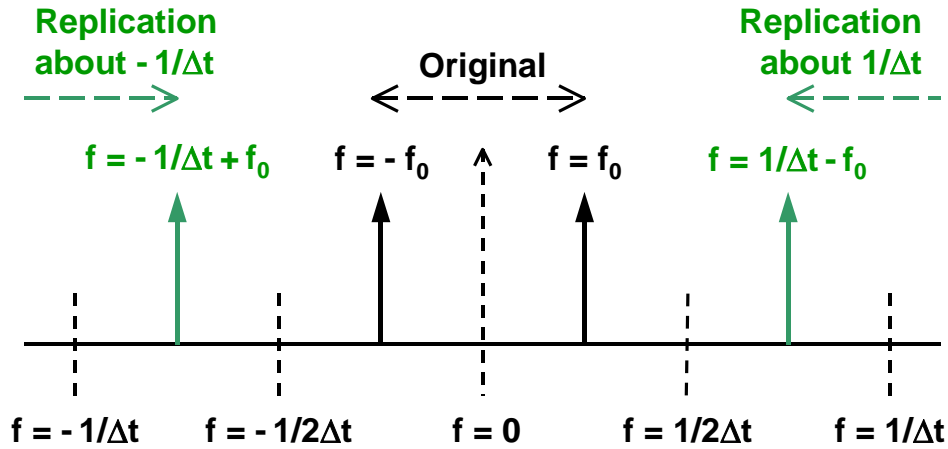

- a.) Consider a simple cosine signal (i.e., a signal with a signal frequency component): $g(t) = \cos(2\pi f_0 t) \Leftrightarrow G(f) = \frac{1}{2} [\delta(f - f_0) + \delta(f + f_0)]$

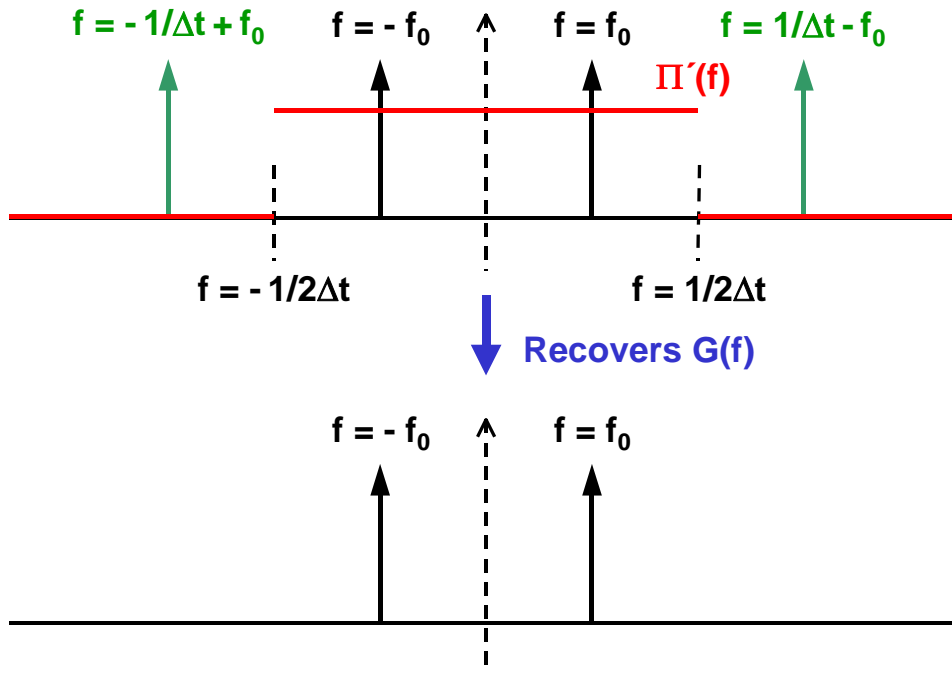

- b.) Let $g(t)$ be sampled at a uniform interval Δt

Earth 460 Classnotes (Set 5)

c.) Case 1: $f_N = 1/2\Delta t > f_0$ (i.e., no overlapping replications)

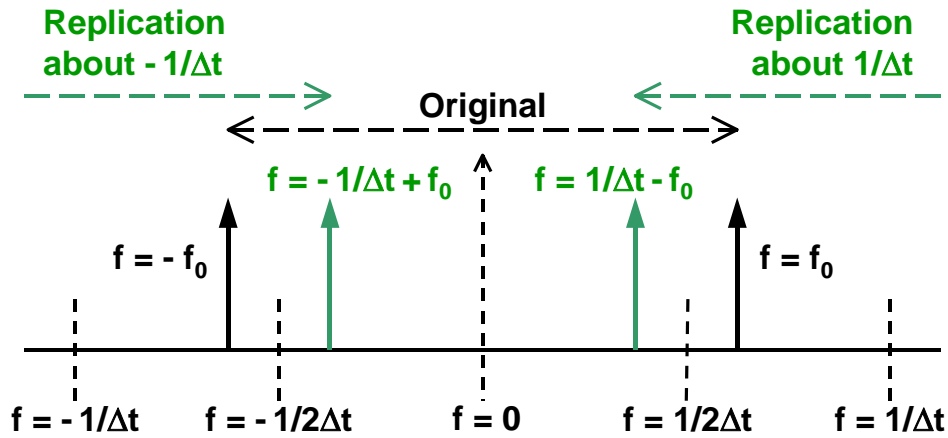

Multiplying $D(f)$ by $\Pi'(f) = \Delta t \Pi(\Delta t f)$ returns $G(f)$

d.) Case 2: $1/\Delta t > f_0 > f_N = 1/2\Delta t$ (i.e., $G(f)$ overlapping with neighboring replication)

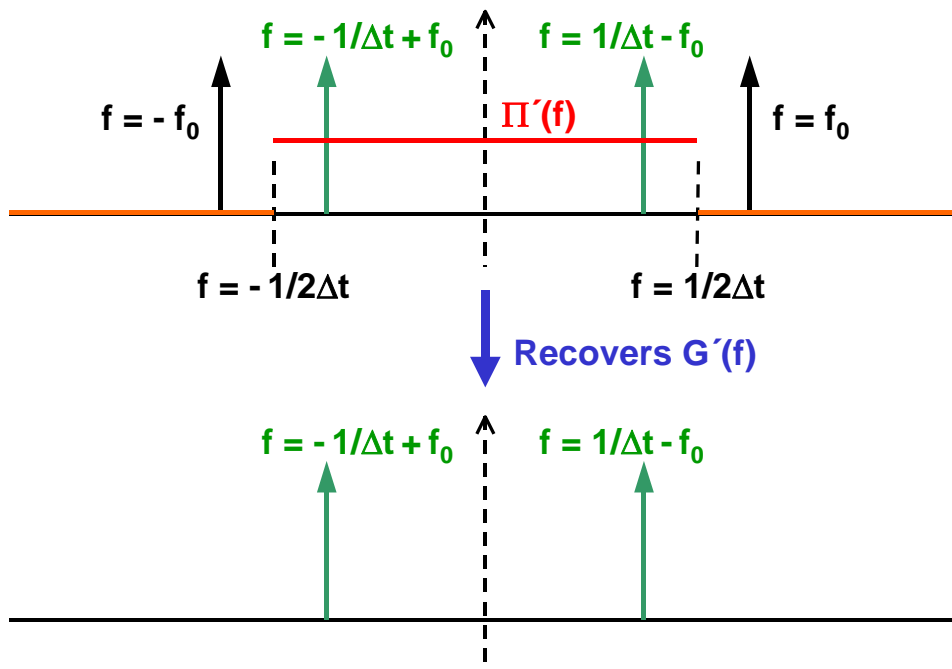

Earth 460 Classnotes (Set 5)

Multiplying $D(f)$ by $\Pi'(f) = \Delta t \Pi(\Delta t f)$ returns

$$G'(f) = \frac{1}{2} \left[\delta(f - (1/\Delta t - f_0)) + \delta(f + (1/\Delta t - f_0)) \right] \text{ where}$$

$$g'(t) = \cos(2\pi(1/\Delta t - f_0)t) \Leftrightarrow G'(f)$$

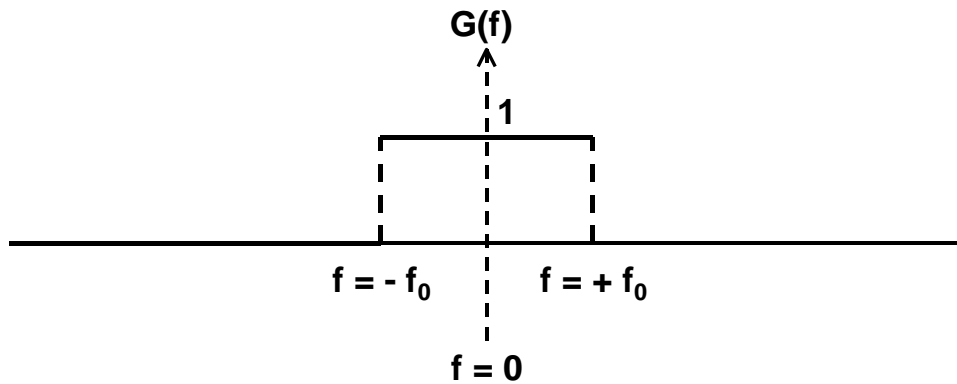

Note: the frequency of the aliased cosine is lower than the original signal by $2f_0 - 1/\Delta t$

Earth 460 Classnotes (Set 5)

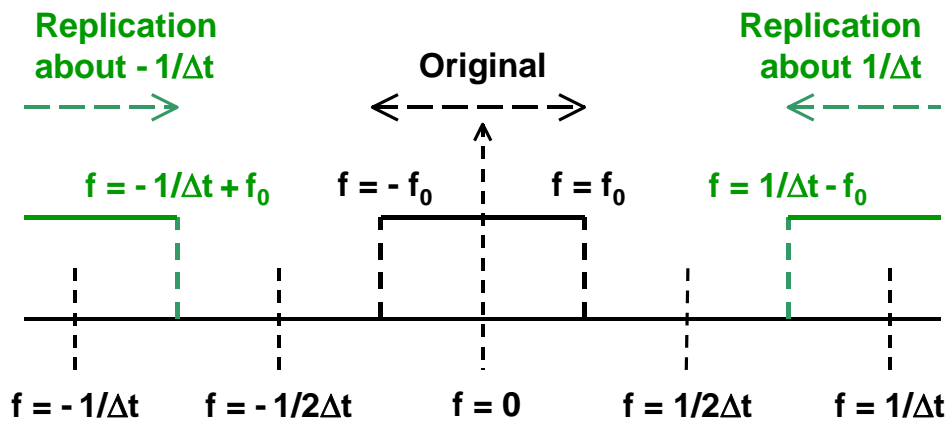

3.) Effects of Overlap due to Aliasing

a.) Consider a simple sine function $g(t) = 2f_0 \text{sinc}(2f_0 t) \Leftrightarrow G(f) = \Pi(f/2f_0)$

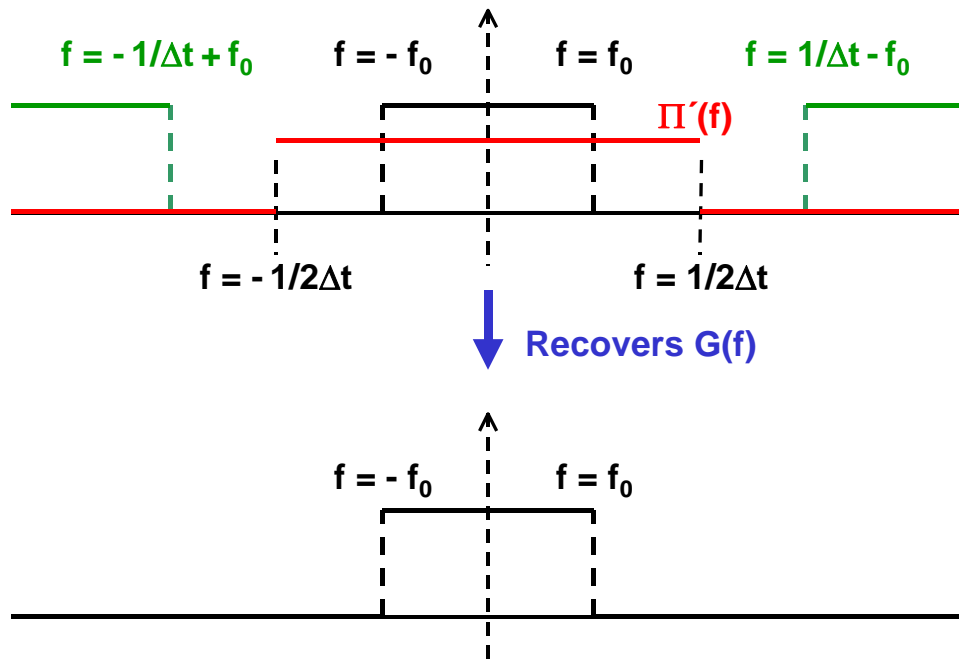

b.) Let $g(t)$ be sampled at a uniform interval Δt

c.) Case 1: $f_N = 1/2\Delta t > f_0$ (i.e., no overlapping replications)

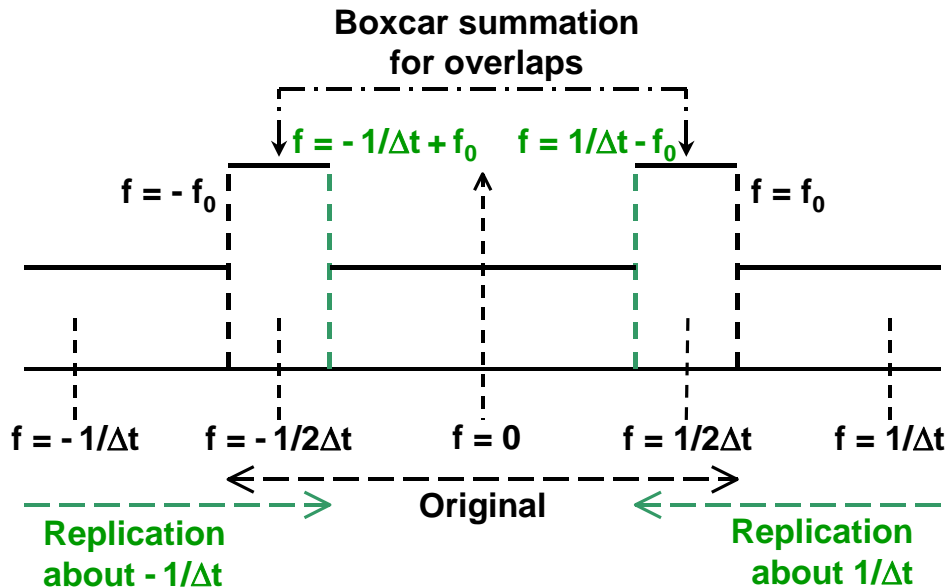

Earth 460 Classnotes (Set 5)

Multiplying $D(f)$ by $\Pi'(f) = \Delta t \Pi(\Delta t f)$ returns $G(f)$

d.) Case 2: $1/\Delta t > f_0 > f_N = 1/2\Delta t$ (i.e., $G(f)$ overlapping with neighboring replication)

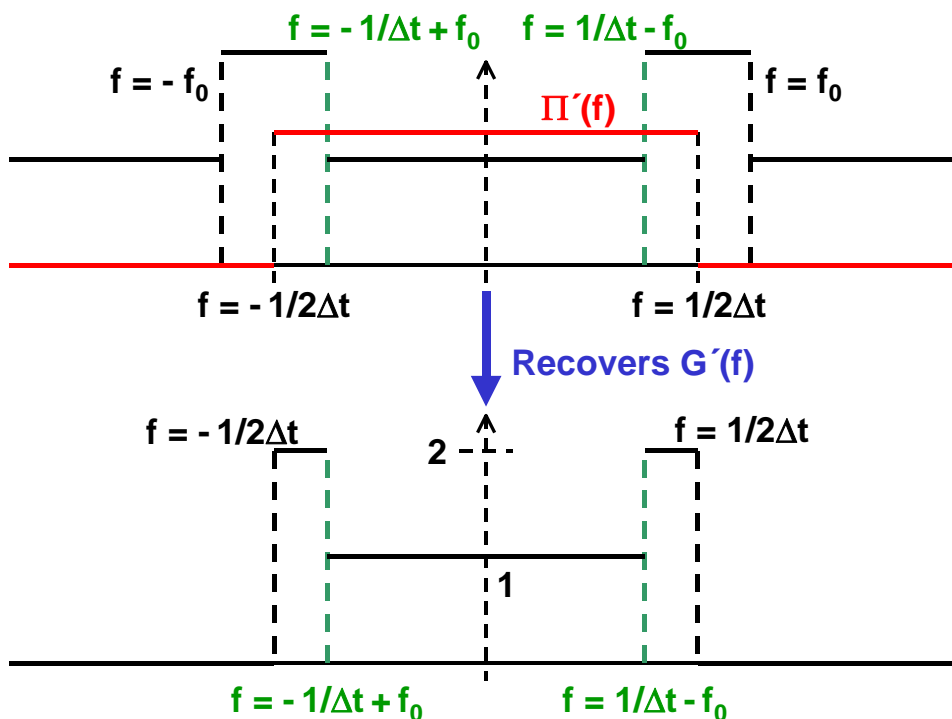

Earth 460 Classnotes (Set 5)

Multiplying $D(f)$ by $\Pi'(f) = \Delta t \Pi(\Delta t f)$ returns

$$G'(f) = 2\Pi(f/2f_N) - \Pi(f/2(1/\Delta t - f_0)) \text{ where}$$

$$g'(t) = 4f_N \text{sinc}(2f_N t) - 2(1/\Delta t - f_0) \text{sinc}(2(1/\Delta t - f_0)t) \Leftrightarrow G'(f)$$

Examples:

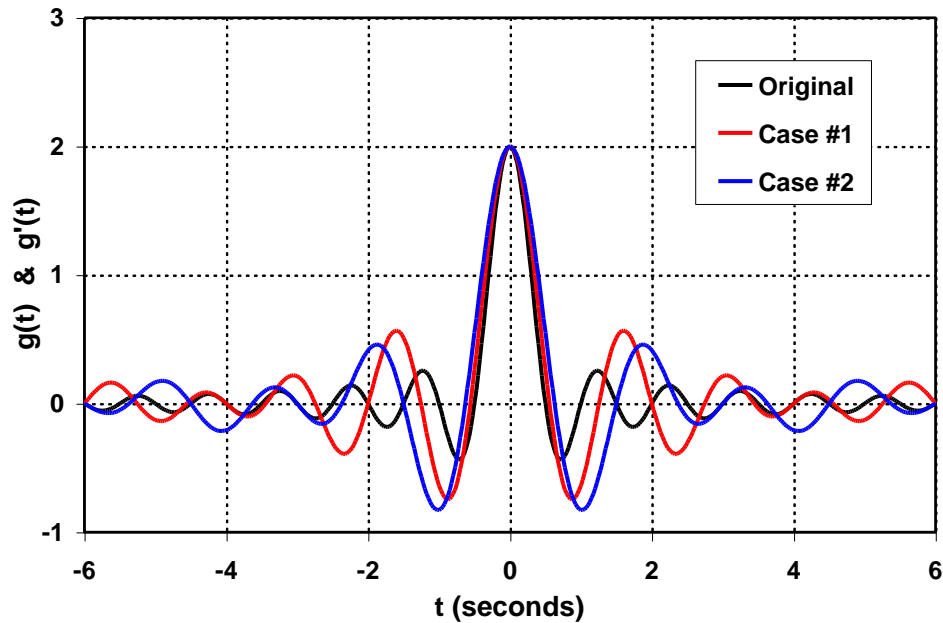

Original signal $g(t) = 2f_0 \text{sinc}(2f_0 t)$ with $f_0 = 1$ Hz

Aliased signal $g'(t) = 4f_N \text{sinc}(2f_N t) - 2(1/\Delta t - f_0) \text{sinc}(2(1/\Delta t - f_0)t) \Leftrightarrow G'(f)$

Case #1: $\Delta t = \frac{2}{3} \text{ s} \rightarrow f_N = \frac{3}{4} \text{ Hz}$

Case #2: $\Delta t = \frac{3}{4} \text{ s} \rightarrow f_N = \frac{2}{3} \text{ Hz}$

Earth 460 Classnotes (Set 5)

4.) Spatial Aliasing

- For a collection of uniformly spaced seismic/GPR traces (e.g., CMP gather, reflection profile), information having a wave number k greater than Nyquist wave number k_N will undergo spatial aliasing.
- If an event has an apparent horizontal velocity v_a , then its temporal frequency component f has a wave number $k = f/v_a$. If $k \geq k_N$, then this frequency component is aliased.
- In f - k space, the effects of spatial aliasing of an event causes *wrap around* of its frequency component having $k \geq k_N$.
- Spatial aliasing is avoided by having sufficiently small spatial sampling Δx or using a low-pass filter to remove temporal frequency components that undergo aliasing.
